

# Number Theory in Oscar: From Class Groups to Class Fields and Beyond

Claus Fieker

June 28, 2023

# Preliminaries

- Mostly in Hecke  
<https://github.com/thofma/Hecke.jl>
- > 200k loc, in Julia
- main maintainer: Tommy Hofmann
- many contributors
- much broader scope than presented

# Why Julia?

- Interactive
- As fast as c
- Solves 2-language problem
- Not maintained by us
- Modern
- Interoperates well with c

# Basics

## Definition

A number field is a finite extension of  $\mathbb{Q}$

- no link to  $\mathbb{C}$
- based in vector space structure
- inefficient in general

# Primitive Element

## Theorem

*For a number field  $K$ , there is some  $\alpha \in K$  s.th.  $K = \mathbb{Q}[\alpha]$ . Furthermore, for the minimal polynomial  $f \in \mathbb{Q}[t]$  of  $\alpha$  we have  $K \cong \mathbb{Q}[t]/f$ .*

- Sonn-Zassenhaus: given a basis, some  $\alpha$  can be found
- mostly, we start with  $f$ , typically monic, integral, irreducible
- interesting fields are often differently given

# Example

```

julia>

# Example

```
julia> using Oscar
```

```

-----      -----      -----      -      -----
|          | |          | |          | | |          |          |
|          | |          |          | | |          |          |
|          | ----- |          | |          | -----
|          |          | |          |-----|          | |
|          | |          | |          |          |          |
-----      -----      -----      -      -      -

```

```
...combining (and extending) ANTIC, GAP, Polymake and Singular
Version 0.12.2-DEV ...
```

```
... which comes with absolutely no warranty whatsoever
```

```
Type: '?Oscar' for more information
```

# Example

```
julia> Qx, x = QQ["x"];
julia> K, a = number_field(x^3-2)
(Number field of degree 3 over QQ, _a)
julia> a^3
2
julia> basis(K)
3-element Vector{nf_elem}:
 1
 _a
 _a^2
```

# More Constructions

Number Fields can be constructed in many other ways:

- special constructs (quadratic fields, cyclotomics)
- splitting fields, normal closures
- subfields
- extensions of number fields (by polynomials)
- *non-simple* fields
- composita

# Examples

```
julia> Ky, y = K["y"];
julia> L, b = number_field(y^3-a)
(Relative number field of degree 3 over number field, _$)
julia> b^3
_a
julia> b^9
2
julia> k, c = number_field([x^2-2, x^2-3, x^2-5])
(Non-simple number field of degree 8 over QQ, NfAbsNSElem[_$1, _$2, _$3])
julia> c[2]^2
3
```

## Primitive Element - 2

The existence theorem is effective:

```
julia> absolute_simple_field(k)
```

```
julia> ka, mp = absolute_simple_field(k);
```

```
julia> ka
```

```
Number field with defining polynomial  $x^8 - 40x^6 + 352x^4 - 960x^2 + 5$   
over rational field
```

```
julia> mp(gen(ka))
```

```
_$1 + _$2 + _$3
```

```
julia> preimage(mp, c[2])
```

```
-1//96*_a^7 + 37//96*_a^5 - 61//24*_a^3 + 15//4*_a
```

# Basics

For arithmetic purposes, one wants to work with rings, in particular the ring of integers, maximal order:

## Definition

$\alpha \in K$  is called integral (algebraic integer) iff the minimal polynomial is monic and integral. The set of all algebraic integers is called the integral closure of  $\mathbb{Z}$  in  $K$  or maximal order  $\mathbb{Z}_K$ .

Actually:

- $\mathbb{Z}_K$  is a ring
- $\mathbb{Z}_K$  is a free  $\mathbb{Z}$ -module of rank  $n = [K : \mathbb{Q}]$
- $\mathbb{Z}_K$  can be computed...

# Examples

```
julia> ZK = maximal_order(K)
```

Maximal order of Number field of degree 3 over  $\mathbb{Q}$   
with basis `nf_elem[1, _a, _a^2]`

```
julia> maximal_order(quadratic_field(5)[1])
```

Maximal order of Real quadratic field defined by  $x^2 - 5$   
with basis `nf_elem[1, 1//2*sqrt(5) + 1//2]`

# Class Group

- The maximal order is a Dedekind domain, hence the ideals form a group. The quotient by principal ideals is finite, the *class group*.
- The class group is trivial iff the maximal order is a PID.
- The class group controls the multiplicative structure of a number field.
- The implementation in Oscar is competitive and was involved in world record computations.

# Examples

```
julia> k, a = quadratic_field(-1009);  
julia> c, mc = class_group(k)  
(GrpAb: Z/20, ClassGroup map of  
Set of ideals of  $O_k$ )
```

```
julia> mc(c[1])  
<11, 117*sqrt(-1009) + 75>  
Norm: 11  
Minimum: 11  
two normal wrt: 11
```

# Examples

```
julia> ans^10
<25937424601, 3178139197528759054702872282444000*sqrt(-1009) - 493511248270
Norm: 25937424601
Minimum: 25937424601
two normal wrt: 11
```

```
julia> I = mc(10*c[1])
<2, 3*sqrt(-1009) + 3>
Norm: 2
Minimum: 2
two normal wrt: 2
```

# Examples

```
julia> is_principal(I)
(false, 1)
```

```
julia> is_principal(I^2)
(true, -2)
```

# Examples

```
julia> factor(3*5*7*order(I))
Dict{NfOrdId1, Int64} with 4 entries:
  <7, -1008>          => 1
  <3, -1005>          => 1
  <5, sqrt(-1009) + 9> => 1
  <5, sqrt(-1009) + 1> => 1
```

```
julia> [preimage(mc, x) for x = keys(ans)]
4-element Vector{GrpAbFinGenElem}:
Element of c with components [0]
Element of c with components [0]
Element of c with components [4]
Element of c with components [16]
```

# Basics

- A *Class Field* is an extension with abelian automorphism group
- Class Fields are parametrized by generalized class groups
- Many properties can be read off the parameters, other not (yet)
- Links to analytic theory
- “Easiest” example: the Hilbert Class Field...
  - Maximal abelian unramified extension
  - Automorphism group isomorphic to class group
  - Every ideal of base becomes principal

# Examples

```
julia> k, a = wildanger_field(3, 13);
```

```
julia> k
```

```
Number field with defining polynomial  $x^3 - 13x^2 + 13x - 13$   
over rational field
```

```
julia> H = hilbert_class_field(k)
```

```
Class field defined mod  $\langle 1, 1 \rangle$ ,  $\text{InfPlc}\{\text{AnticNumberField}, \text{Hecke.NumFieldEm}\}$   
of structure Abelian group with structure:  $\mathbb{Z}/9$ 
```

# Examples

```
julia> galois_group(H)
Group([ (1,2,3,4,5,6,7,8,9) ])
```

```
julia> discriminant(H)
<1, 1>
Norm: 1
Minimum: 1
principal generator 1
two normal wrt: 1
```

# Examples

```
julia> K = number_field(H)
```

Non-simple number field with defining polynomials

```
[x^9 + (-54*_x^2 + 648*_x - 567)*x^7 + (27*_x^2 - 216*_x - 3780)*x^6 + (-2
  over number field with defining polynomial x^3 - 13*x^2 + 13*x - 13
  over rational field
```

```
julia> Ka, mp = absolute_simple_field(K);
```

```
julia> class_group(Ka)
```

```
(GrpAb: Z/1, ClassGroup map of
Set of ideals of O_Ka)
```

# Field Factory

## Theorem (Shafarevich)

*Every solvable group occurs as a Galois group over  $\mathbb{Q}$ .*

- Every solvable group is a chain of abelian (cyclic) groups
- Every solvable field is a tower of class fields
- Most towers yield the wrong group
- Sircana automated this completely

# Examples

```
julia> small_group(8, 3)
<pc group of size 8 with 3 generators>
```

```
julia> describe(ans)
"D8"
```

```
julia> fields(8, 3, ZZ(10)^7)
7-element Vector{Hecke.FieldsTower}:
  Field context for the number field defined by  $x^8 + 6x^4 + 1$ 
  Field context for the number field defined by  $x^8 - 2x^7 + 7x^6 - 14x^5 + 7x^4 - 14x^3 + 7x^2 - 14x + 7$ 
  ...
```

# Galois Groups

Carefully distinguish:

**Galois Group** vs. **Automorphism Group**

Fact (Automorphism Group)

*The group of actual endomorphisms of the field*

Fact (Galois Group)

*For roots  $\alpha_1, \dots, \alpha_n$ , the group of legal permutations of those roots.*

# Examples

```
julia> k, a = cyclotomic_field(5);  
julia> automorphism_group(PermGroup, k)  
(Group([ (1,2,3,4) ]), Composite map consisting of the following
```

```
Group([ (1,2,3,4) ]) -> Generic group of order 4 with multiplication table  
then  
Generic group of order 4 with multiplication table -> Set of automorphisms  
)
```

```
julia> galois_group(k)  
(Group([ (1,4,2,3), (1,2)(3,4) ]), Galois Context for  $x^4 + x^3 + x^2 + x - 1$ )
```

# Examples

```
julia> k, a = wildanger_field(3, 13);  
julia> automorphism_group(PermGroup, k)  
(Group()), Composite map consisting of the following
```

```
Group() -> Generic group of order 1 with multiplication table  
then
```

```
Generic group of order 1 with multiplication table -> Set of automorphisms  
)
```

```
julia> galois_group(k)  
(Sym( [ 1 .. 3 ] ), Galois Context for  $x^3 - 13x^2 + 13x - 13$  and prime  $13$ )
```

# Examples

```
julia> g, s = galois_group(k);  
julia> roots(s, 5)  
3-element Vector{qadic}:  
 4*7^0 + 6*7^1 + 2*7^2 + 0(7^3)  
 (5*7^0 + 4*7^2 + 0(7^3))*a + 2*7^0 + 3*7^1 + 0(7^3)  
 (2*7^0 + 6*7^1 + 2*7^2 + 0(7^3))*a + 6*7^1 + 3*7^2 + 0(7^3)
```

# Examples

```
julia> n = normal_subgroups(g)
3-element Vector{PermGroup}:
 Sym( [ 1 .. 3 ] )
 Alt( [ 1 .. 3 ] )
 Group(())
```

```
julia> fixed_field(s, n[2])
Number field with defining polynomial  $x^2 + 59488$ 
over rational field
```

```
julia> fixed_field(s, n[3])
Number field with defining polynomial  $x^6 - 26x^5 + 178659x^4 - 3093740x^3 + 178659x^2 - 26x + 1$ 
over rational field
```

# Solvability

Classically solvability is linked to explicit ways to write the roots of a polynomial in terms of (nested) radicals.

This is possible iff the associated Galois group is solvable - and the usual proof is constructive...

# Examples

```
julia> solve(x^3+x+1)
```

```
(Relative number field of degree 3 over relative number field, Any[((1//9)*
```

```
julia> ans[1]
```

```
Relative number field ...  $x^3 + (3z_3 + 3//2)a_2 + 27//2$ 
```

```
over relative number field ...  $x^2 + 31$ 
```

```
over number field ...  $x^2 + x + 1$ 
```

```
over rational field
```

# Examples

```
julia> h = Hecke.fields(8, 3, ZZ(10)^7);
```

```
julia> solve(h[1])
```

```
(Relative number field of degree 2 over relative number field, Any[a3 + 1/
```

```
julia> ans[1]
```

```
Relative number field ...  $x^2 + 1/2$ 
```

```
over relative number field ...  $x^2 + a1 - 2$ 
```

```
over number field ...  $x^2 + 4$ 
```

```
over rational field
```

# Representations

Building on top of the Gap character theory and the class field theory we can do interesting computations...

Let  $G = 24T201$  of order 240. The 9-th character of  $G$  has Schur index 2, character field  $\mathbb{Q}$ . The representation, in Gap, is constructed over  $\mathbb{Q}(\zeta_5)$ .

The representation should live over a quadratic field, however, not over  $\mathbb{Q}[\sqrt{5}]$ .

# Example

```
julia> G = transitive_group(24, 201);
julia> order(G)
240
julia> T = character_table(G)[9];
julia> R = gmodule(T)
G-module for t24n201 acting on Vector space of dimension 6
over abelian closure of Q

julia> R = gmodule(CyclotomicField, R)
G-module for t24n201 acting on Vector space of dimension 6
over cyclotomic field of order 5
```

# Example

```
julia> schur_index(T)  
2
```

```
julia> character_field(T)  
(Cyclotomic field of order 1, Map from  
Cyclotomic field of order 1 to Abelian closure of  $\mathbb{Q}$  defined by a julia-fun
```

# Example

```
julia> gmodule_minimal_field(R)
```

```
G-module for t24n201 acting on Vector space of dimension 6  
over number field of degree 4 over QQ
```

```
julia> B, mB = relative_brauer_group(base_ring(R), character_field(R))
```

```
(Relative Brauer group for Cyclotomic field of order 5 over Number field of  
, Map from
```

```
Relative Brauer group for Cyclotomic field of order 5 over Number field of  
to AllCoChains{2, PermGroupElem, MultGrpElem{nf_elem}}() defined by a julia
```

# Example

```
julia> B(R)
Dict{Union{NumFieldOrdId1, Hecke.NumFieldEmb}, Hecke.QmodnZElem}(
  <2, 2>
  two normal wrt: 2 => 1//2 + Z,
  Complex embedding corresponding ... => 1//2 + Z)
```

## Example

```
julia> grunwald_wang(Dict{2*ZZ => 2}, Dict{complex_embeddings(QQ)[1] => 2})
Class field defined mod (<8, 8>, InfPlc{AnticNumberField, Hecke.NumFieldEm
```

```
julia> absolute_simple_field(number_field(ans))
(Number field of degree 2 over QQ, Map with following data
Domain:
=====
Number field of degree 2 over QQ
Codomain:
=====
Non-simple number field of degree 2 over number field ...
```

## Example

```
julia> compositum(base_ring(R), ans[1])
(Number field of degree 8 over QQ, Map with following data
Domain:
=====
Cyclotomic field of order 5
Codomain:
=====
Number field of degree 8 over QQ, Map with following data
Domain:
=====
Number field of degree 2 over QQ
Codomain:
=====
```

# Example

```
julia> gmodule_over(ans[3], gmodule(ans[1], R))  
G-module for t24n201 acting on Vector space of dimension 6  
over number field of degree 2 over QQ
```

```
julia> base_ring(ans)  
Number field with defining polynomial  $x^2 + 2$   
over rational field
```

# Galois Cohomology

## Theorem (Shafarevich)

Let  $K/k$  be abelian and  $k/\mathbb{Q}$  normal, then canonically

$$H^2(\text{Aut}(k/\mathbb{Q}), C_k) = \langle \delta \rangle$$

is cyclic of order  $n = k : \mathbb{Q}$ . Furthermore

$$1 \rightarrow \text{Aut}(K/k) \rightarrow \text{Aut}(K/\mathbb{Q}) \rightarrow \text{Aut}(k/\mathbb{Q}) \rightarrow 1$$

is exact, and

$$H^2(\text{Aut}(k/\mathbb{Q}), \text{Aut}(K/k)) \ni \text{Aut}(K/\mathbb{Q}) = \rho(\delta)$$

for the canonical projection  $\rho : C_k \rightarrow \text{Aut}(K/k)$

# Chinburg

$C_k$ , the idel class group, is neither finite, nor finitely presented nor are its elements.

## Theorem (Chinburg)

*There exists a finitely presented module that is cohomologically equivalent to the idel class group  $C_k$ .*

- Debeerst (PhD with Bley) made it algorithmic
- Aslam improved the local part
- Implemented in Oscar
- Can compute the local fundamental class
- Can compute global class in many cases

## Example

```
julia> k, a = quadratic_field(2);
julia> A = abelian_extensions(k, [2], ZZ(10)^4,
                        signatures = [(4,0)]);
julia> a = A[findall(is_normal, A)];
julia> [describe(galois_group(x, QQ)[1]) for x = a]
3-element Vector{String}:
 "C2 x C2"
 "C2 x C2"
 "C4"
julia> [describe(galois_group(x, QQ)[1]) for x = A]
15-element Vector{String}:
 "C2 x C2"
 "D8"
```
