

# Smooth trajectories in straight line mazes

Yves Bertot

Joint work with Thomas Portet, Quentin Vermande

April 2023

# The game

- ▶ Find a smooth path in a maze
- ▶ Decompose the problem
  - ▶ Find a discrete approximation of the problem
  - ▶ Construct a broken line (non-smooth path)
  - ▶ smoothen the angles
- ▶ Prove the correctness of the algorithm
  - ▶ Prove the absence of collision
  - ▶ work in progress
  - ▶ Ideally one should also prove that a path is found as soon as one exists

# Cell decomposition

- ▶ Decompose the space into simple cells
- ▶ Each cell is convex
- ▶ Each cell is free of obstacles
- ▶ Each cell may have neighbours where moving is safe

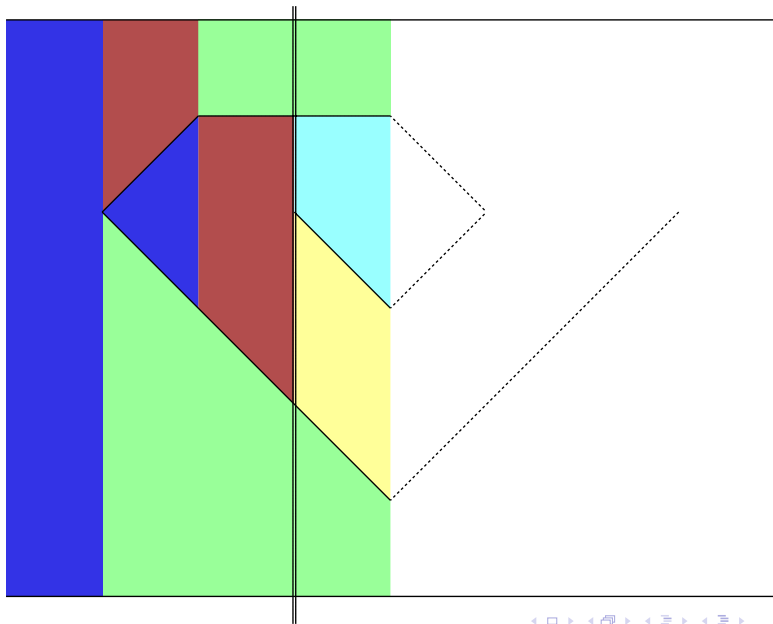

# Vertical cell decomposition

- ▶ Use a vertical sweep line moving left to right
- ▶ Stop each time one meets an edge tip (an event)
- ▶ maintain a vertically ordered sequence of open cells
  - ▶ close all open cells in contact with the event
  - ▶ open new cells for all edges starting at this event
- ▶ Simplifying assumptions
  - ▶ No vertical edges
  - ▶ Edges do not cross

# Intermediate position for vertical cell decomposition (1)

## Intermediate position for vertical cell decomposition (2)

## Difficulty with vertically aligned events

- ▶ Closed cells may be degenerate
  - ▶ Left and right side are in contact
- ▶ Solution: special treatment
  - ▶ Add points to the right side of last closed cell
  - ▶ Add points to the left side of last opened cell

## Vertical cell decomposition example

# Cell assumptions

- ▶ Vertical edges are safe passages between two cells
- ▶ Moving directly left-edge right-edge is safe
  - ▶ and vice-versa
- ▶ Moving from a left-edge to the cell center is safe
  - ▶ similarly for a right-edge
  - ▶ moving from left-edge to left-edge is safe by going through the cell center

## Finding a path in the cell graph

- ▶ A discrete path from cell to cell is found by breadth-first search
- ▶ Connected components of the graph are defined by polygons
- ▶ Special care for points that are already on the common edge of two cells

## Making a broken line path between points

- ▶ Find the cells containing the points
- ▶ Find a discrete path between cell names
- ▶ Make a path from vertical edge midpoint to vertical edge midpoint
- ▶ Connect the source and target point to the first and last vertical edge midpoints
  - ▶ Unless the source or targets are themselves on a vertical edge

## broken line safe path between points

## Making corners smooth

- ▶ Angles would require a robot to stop to turn
- ▶ rounded bends makes it possible to keep moving
- ▶ First approximation: no limit on steering radius
- ▶ Using quadratic Bezier curves for this purpose

# The basics of quadratic Bézier curves

- ▶ Bézier curves are given by a set of control points (3 for a quadratic curve)
- ▶ Points on the curves are obtained by computing weighted barycenters
  - ▶ The curve is enclosed in the convex hull of the control points
- ▶ Given control points  $a_0, a_1, \dots, a_{n-1}, a_n$ ,  $a_0, a_1$  is tangent to the curve in  $a_0$ 
  - ▶ same for  $a_{n-1}, a_n$  in  $a_n$

## Bezier curve illustration

- ▶ Straight edge tips of this drawing are control points
- ▶ The curve is inside the triangle

## Plotting the Bezier curve

- ▶ Show how the point for ratio  $4/9$  is computed
- ▶ Control points for the two subcurves are given by the new point, the initial starting and end points, and the solid green straight edge tip

## Using Bezier curves for smoothing

- ▶ Add extra points in the middle of each straight line segment
- ▶ Uses these extra points as first and last control points for Bezier curves
- ▶ Use the angle point as the middle control point
- ▶ Check the Bezier curve for collision and repair if need be

# Checking for collision

- ▶ Two kinds of angles
- ▶ Angles at cell center: in the middle of safe space
  - ▶ No risk of collision
- ▶ angles at vertical edge midpoint
  - ▶ Use dichotomy until a guaranteed result is obtained
  - ▶ To compute control points in dichotomy, only half sums are needed

## Collision checking, graphically

## Not passing in the safe zone

## Repairing a faulty curve

- ▶ Simple solution: bring the control points closer to the corner
- ▶ Use the first half points computed in the checking phase
- ▶ Check and repair again recursively, if need be

## Constructing a repaired curve

## Checking the repaired curve

- ▶ The one-triangle convex hull is given by the dashed line
- ▶ It does not make it possible to conclude
- ▶ After dichotomy, the solid lines do

# Final trajectories

## Final trajectories: repaired curve example

# Proof tools

- ▶ Breadth first search (recent development)
- ▶ Convex hulls (Pichardie & B. 2001)
  - ▶ Orientation predicate
  - ▶ Collision between two segments (recent development)
- ▶ Convex spaces and Bezier Curve
  - ▶ Internship by Q. Vermande
  - ▶ Using `infotheo`, especially convex and conical spaces (Affeldt & Garrigue & Saikawa 2020)
- ▶ Bernstein Polynomials (B. & Guilhot & Mahboubi, 2010, Zsido 2013)

# Key proof features

- ▶ Replaced absence collision by guarantees to travel inside a safe subset
  - ▶ interior of cells (2-dimensional subsets)
  - ▶ interior of doors (1-dimensional subsets)
- ▶ Safe paths from cell centers to all doors to other cells
- ▶ Safe path from any door on the left side to a door on the right side of a cell
  - ▶ This requires cells to have distinct left and right sides
- ▶ Bezier curves that cross doors are monotonic in the first coordinate
  - ▶ It is enough to prove that the door is passed correctly
- ▶ work in progress

## Two uses of dichotomy

- ▶ In the algorithm, dichotomy at midpoints
  - ▶ Obtain triangles that hug the curve close enough
  - ▶ Obtain guarantee that any intersection with the vertical line is within the door
  - ▶ Does not obtain unicity
- ▶ In the proof, dichotomy at the exact value
  - ▶ Proves that the door is passed only once

# Cell properties

- ▶ Two edges for the low and high side
  - ▶ These edges do not cross
- ▶ Two sequences of points for the left and right side
  - ▶ Non-empty
  - ▶ Vertically aligned points,
  - ▶ Sorted with respect to their second coordinates
  - ▶ First and last point must be on low and high edges
- ▶ Left and right side must be at distinct first coordinate

## Further work

- ▶ This is proof-of-concept, not satisfactory for practical use
  - ▶ Path from middle of door to middle of door is too naive
  - ▶ Bezier Curve do not guarantee pleasant dynamics
- ▶ Should consider Clothoids
- ▶ Should improve Coq to facilitate plotting parameterized curves
  - ▶ Current approach by generating postscript programs from algorithm data
  - ▶ Rely on Postscript's Bezier curves (slides 14, 26, 27, 28)
